PYRAZINE DERIVATIVES AS MODULATORS OF TYROSINE KINASES

FIELD OF THE INVENTION

5 This invention claims priority from U.S. Provisional Application No. 60/233,968 filed September 20, 2000 and entitled "Pyrazine Derivatives as Modulators of Tyrosine Kinases."

The present invention provides pyrazine derivatives that inhibit tyrosine kinase activity. Certain pyrazine derivatives are selective inhibitors of the vascular endothelial growth factor (VEGF) receptor tyrosine kinase. The present invention also provides pharmaceutical formulations containing the pyrazine derivatives and methods for use of these formulations as anti-tumor agents, and to treat diabetic retinopathy, rheumatoid arthritis, endometriosis, and psoriasis.

15 BACKGROUND OF THE INVENTION

Angiogenesis plays a role in various processes including development of the vasculature, wound healing and maintenance of the female reproductive system. Pathological angiogenesis is associated with disease states such as cancer, diabetic retinopathy, rheumatoid arthritis, endometriosis and psoriasis. Solid-tumor cancers, in particular, are dependent on angiogenesis for their growth. The vascular endothelial growth factors (VEGFs) are mediators of both normal and pathologic angiogenesis. VEGF transmits signals into cells through their cognate receptors, which belong to the receptor tyrosine kinase (RTK) family of transmembrane receptors. These receptors are tripartite, consisting of an extracellular ligand-binding domain, a transmembrane domain, which anchors the receptor in the membrane of the cell, and an intracellular tyrosine kinase domain. One subfamily of RTKs comprises the receptors Flt1/VEGF-R1 and KDR/Flk1/VEGF-R2, which bind VEGFs. Binding of the VEGF ligand to the receptor results in stimulation of the receptor tyrosine kinase activity and transduction of biological signals into the cell. The KDR/Flk1/VEGF-R2 receptor mediates the biological activities of mitogenesis and proliferation of endothelial cells while the Flt1/VEGF-R1 receptor mediates functions such as endothelial cell adhesion. Inhibition of KDR/Flk1/VEGF-R2 signalling has been

shown to inhibit the process of angiogenesis. Inhibitors of this receptor are likely useful in controlling or limiting angiogenesis.

SUMMARY OF THE INVENTION

- 5 The present invention provides pyrazine derivative compounds that display activity as kinase inhibitors of the formula:

- where the substituents are defined herein. These pyrazine derivatives are useful as kinase inhibitors; particularly, as inhibitors against the kinase domain of the Vascular Endothelial Growth Factor Receptor (VEGF-R), inhibiting the activity of the VEGF receptor *in vitro* and *in vivo*.

The compounds of the present invention may also be present in the form of pharmaceutically acceptable salts. For use in medicine, the salts of the compounds of this invention refer to non-toxic "pharmaceutically acceptable salts" (Ref. *International J. Pharm.*, 1986, 33, 201-217; *J. Pharm.Sci.*, 1997 (Jan), 66, 1, 1). Other salts may, however, be useful in the preparation of compounds according to this invention or of their pharmaceutically acceptable salts. Representative organic or inorganic acids include, but are not limited to, hydrochloric, hydrobromic, hydriodic, perchloric, sulfuric, nitric, phosphoric, acetic, propionic, glycolic, lactic, succinic, maleic, fumaric, malic, tartaric, citric, benzoic, mandelic, methanesulfonic, hydroxyethanesulfonic, benzenesulfonic, oxalic, pamoic, 2-naphthalenesulfonic, *p*-toluenesulfonic, cyclohexanesulfamic, salicylic, saccharinic or trifluoroacetic acid. Representative organic or inorganic bases include, but are not limited to, basic or cationic salts such as benzathine, chlorprocaine, choline, diethanolamine, ethylenediamine, meglumine, procaine, aluminum, calcium, lithium, magnesium, potassium, sodium and zinc.

To the extent that certain compounds of the present invention may have at least one chiral center, the compounds may thus exist as enantiomers. In addition, the compounds of the present invention may also possess two or more chiral centers and thus may also exist as diastereomers or as exo or endo isomers. Where the processes for the preparation of the present compounds give rise to a mixture of stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. Accordingly, the compounds may be prepared as a racemic mixture or, by either enantiospecific synthesis or resolution, as individual enantiomers. The compounds may, for example, be resolved from a racemic mixture into their component racemates by standard techniques, such as the formation of diastereomeric pairs by salt formation with an optically active acid, such as (-)-di-*p*-toluoyl-*d*-tartaric acid and/or (+)-di-*p*-toluoyl-*l*-tartaric acid followed by fractional crystallization and regeneration of the free base. The racemic mixture may also be resolved by formation of diastereomeric esters or amides, followed by chromatographic separation and removal of the chiral auxiliary. Alternatively, the compounds may be resolved using a chiral HPLC column. It is to be understood that all such isomers and mixtures thereof are encompassed within the scope of the present invention.

During any of the processes for preparation of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in Protective Groups in Organic Chemistry, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

10

Furthermore, some of the crystalline forms for the compounds may exist as polymorphs and as such are intended to be included in the present invention. In addition, some of the compounds may form solvates with water (i.e., hydrates) or common organic solvents, and such solvates are also intended to be encompassed within the scope of this invention.

15

The present invention includes compounds that are useful in the treatment of diseases associated with the stimulation and presentation of inappropriate, abnormal or increased angiogenesis; for example excessive angiogenesis that is associated with some proliferative diseases or disease states including, but not limited to diabetic retinopathy, rheumatoid arthritis, endometriosis and psoriasis.

20

Inappropriate or aberrant angiogenesis is also associated with cancer, and in particular, cancers associated with foci of proliferating cells. For purposes of this invention the term "cancer" refers to angiogenesis associated with uncontrolled cell proliferation. Cancers can be benign or malignant and refers to any group for cells that have lost their normal regulatory controls that would otherwise govern the rate of cell growth. Some cancer cells stimulate ingrowth of the vasculature, also referred to as neovascularization, to facilitate survival. Neovascularization further facilitates metastasis. The cancer cells spread throughout the body and invade normal tissues where they proliferate and form secondary cancers. These masses of cancer cells are also referred to as tumors. Tumors, and in particular, solid tumors, require the process of

25

30

angiogenesis to supply oxygen and nutrients. Without a blood supply a tumor can only grow to the size of a few millimeters. Angiogenesis inhibitors inhibit neovascularization and are therefore effective inhibit cancer cell growth in a variety of cancers that require the ingrowth of the microvasculature. Such tumors include for example, breast cancers, pancreatic cancer, skin cancers, including melanomas and basal cell carcinomas, a variety of cancers of the lung, prostate cancers, ovarian cancers, brain cancers, liver cancers, renal and hepatic cancers, uterine cancers, cancers of the gastrointestinal system, colorectal cancers, cancers of the head and neck, including cancers of the mouth and throat,

10

In these diseases, aberrant angiogenesis can be controlled through the use of angiogenesis inhibitors. These inhibitors are molecules that bind to cell receptors, generally on endothelial cells, that are known to be associated with the formation of neovasculature and inhibit receptor signalling pathways resulting in an inhibition of neovascularization. Such receptors include the Vascular Endothelial Growth Factors, such as VEGF-1, 2, 3 and others described below that have been implicated in angiogenesis.

15

Pyrazine Derivative Compounds

Certain pyrazine compounds, described herein, are useful as tyrosine kinase inhibitors, particularly as inhibitors of the kinase domain of VEGF-R (Vascular endothelial growth factor receptor-2, Genbank Accession number X61656), EGFR (epidermal growth factor receptor), GSK-3 β (glycogen synthase kinase-3 beta subunit), PDGF-R (platelet derived growth factor receptor), and FGF-R2 (fibroblast growth factor receptor-2). Preferably, compounds of the present invention are selective inhibitors of the VEGF-R.

20

25

Useful inhibitory activity is defined herein as an IC₅₀ of less than 10 μ M (10 micromolar); preferably, inhibitory activity is less than or equal to 5 μ M; and, more preferably, inhibitory activity is less than or equal to 1 μ M. Using methods well known in the art and/or using the methods provided in the example *infra*, compounds of the present invention may be tested for their ability to inhibit the enzymatic activity of other kinases.

Concentrating and purifying the solution by flash chromatography (using a solvent such as EtOAc/hexane) gives *N*-(R_{10})-2-amino-6-bromopyridine which is then mixed with dry DMF and to the solution is added bromo-(CH_2)_{*m*}-*tert*-butyldimethylsilane and Cs_2CO_3 . The solvent is removed under reduced pressure and the residue chromatographed over silica gel (using a solvent such as ethyl acetate/hexane) to give Compound 7C as a clear oil. A mixture of Compound 7C, Compound 5B, dichlorobis(triphenylphosphine)palladium and LiCl in anhydrous toluene is stirred at 100 °C for 3 h under nitrogen. The cooled reaction mixture is concentrated under vacuum and purified by flash chromatography to give Compound 7D as a yellow oil. A saturated NH_4OH solution is added to the residue until made basic and is followed by adding water to precipitate the solid. The precipitated solid is collected through

filtration, washed with water and Et₂O, and dried under vacuum to provide the target Compound **7E** as a yellow solid.

Scheme 8

As an alternate substitution pattern for Scheme 7, target compounds of the invention may be obtained by mixing 4-iodopicolinic acid Compound **8A** (optionally substituted with R_7) (prepared as described in Lohse, O. *Synth. Commun.* 1996, 26, 2017), DPPA and triethylamine in *t*-BuOH and toluene, heating the mixture at 65 °C for 1.5 h and then at 100 °C for 4 h. Scheme 9

As an alternate substitution pattern for Scheme 7, target compounds of the invention wherein R₇ is selected from halogen may be obtained by adding bromine dropwise to a suspension of 6-aminonicotinic acid Compound **9A** in water at 4 °C. After completion of the addition, the cooling bath is removed and the reaction mixture is stirred at room temperature for 4.5 h. Saturated Na₂S₂O₅ is added slowly to the stirred mixture. The solid is then collected through filtration, washed with water, and dried under vacuum overnight to give a 6-amino-5-bromonicotinic acid intermediate along with a 3,5-dibromo-2-aminopyridine intermediate in approximately a 1:1 ratio as a greenish solid. A mixture of the solid containing the 6-amino-5-bromonicotinic acid intermediate, DPPA, triethylamine, an R₁₀ protecting group such as benzyl alcohol and toluene is heated at 70 °C for 1h, then 100 °C for 1h. After concentrating the reaction

mixture and purification by flash chromatography (using a solvent such as EtOAc/hexane), the Compound **9B** is obtained as a yellow solid. A mixture of Compound **9B**, bromo- $(\text{CH}_2)_m$ -*tert*-butyldiphenylsilane and Cs_2CO_3 in dry DMF is heated at 70°C for 3h. The reaction mixture is concentrated and purified by column chromatography (using a solvent such as EtOAc/hexane) to give Compound **9C** as a yellow oil. To the solution of Compound **9C** in CH_2Cl_2 at 4°C is added NOBF_4 (nitrosonium tetrafluoroborate). After 1h at 4°C , more NOBF_4 is added followed by the same amount of NOBF_4 after another 1h. After stirring for a total of 3h at 4°C , water is added. The aqueous solution is extracted with a solvent such as CH_2Cl_2 . The combined organic layers are dried, concentrated and flash chromatographed (using a solvent such as EtOAc/hexane) to give Compound **9D** as a yellow oil. Other compounds of the invention may be obtained by substituting Compound **9D** for Compound **7C** in the reaction described for use of Compound **7C** in Scheme 7.

ProDrugs

The present invention includes within its scope prodrugs of the compounds of this invention. In general, such prodrugs will be functional derivatives of the compounds which are readily convertible *in vivo* into the required compound. Thus, in the methods of treatment of the present invention, the term "administering" shall encompass the treatment of the various disorders described with the compound specifically disclosed or with a compound which

may not be specifically disclosed, but which converts to the specified compound *in vivo* after administration to the subject. Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in "Design of Prodrugs", ed. H. Bundgaard, Elsevier, 1985.

5

Pharmaceutical formulations

The instant pharmaceutical composition can be prepared according to conventional pharmaceutical techniques. A pharmaceutically acceptable carrier may be used in the composition of the invention. The composition may take a
10 wide variety of forms depending on the form of preparation desired for administration including, but not limited to, intravenous (both bolus and infusion), oral, nasal, transdermally, topical with or without occlusion, intraperitoneal, subcutaneous, intramuscular, or parenteral, all using forms well known to those of ordinary skill in the pharmaceutical arts. In preparing the
15 compositions in oral dosage form, one or more of the usual pharmaceutical carriers may be employed, such as water, glycols, oils, alcohols, flavoring agents, preservatives, coloring agents, syrup and the like in the case of oral liquid preparations (for example, suspensions, elixirs and solutions), or carriers such as starches, sugars, diluents, granulating agents, lubricants, binders, disintegrating
20 agents and the like in the case of oral solid preparations (for example, powders, capsules and tablets).

The compounds may alternatively be administered parenterally via injection of a formulation consisting of the active ingredient dissolved in an inert
25 liquid carrier. The injectable formulation can include the active ingredient mixed with an appropriate inert liquid carrier. Acceptable liquid carriers include vegetable oils such as peanut oil, cotton seed oil, sesame oil, and the like, as well as organic solvents such as solketal, glycerol formal, and the like. As an alternative, aqueous parenteral formulations may also be used. For example,
30 acceptable aqueous solvents include water, Ringer's solution and an isotonic aqueous saline solution. Further, a sterile non-volatile oil can usually be employed as solvent or suspending agent in the aqueous formulation. The formulations are prepared by dissolving or suspending the active ingredient in the liquid carrier such that the final formulation contains from 0.005 to 10% by

weight of the active ingredient. Other additives including a preservative, an isotonizer, a solubilizer, a stabilizer and a pain-soothing agent may adequately be employed.

5 The compounds may alternatively be administered occularly via application of a formulation consisting of the active ingredient dissolved in an inert aqueous liquid carrier. Such aqueous liquid formulations are useful, for example in the treatment of diabetic retinopathy. Acceptable aqueous solvents include water, Ringer's solution, and an isotonic aqueous saline solution. The
10 formulations are prepared by dissolving or suspending the active ingredient in the liquid carrier such that the final formulation contains from 0.005 to 10% by weight of the active ingredient. Other additives including a preservative, an isotonizer, a solubilizer, a stabilizer and a pain-soothing agent may adequately be employed.

15 The compounds of the present invention can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes containing delivery systems as well known in the art are formed from a variety of phospholipids,
20 such as cholesterol, stearylamine or phosphatidylcholines.

 As used herein, a "therapeutically effective amount" of the instant pharmaceutical composition, or compound therein, means an amount that inhibits the function of the kinase enzymatic activity. The instant
25 pharmaceutical composition will generally contain a per dosage unit (e.g., tablet, capsule, powder, injection, teaspoonful and the like) from about 0.001 to about 100 mg/kg. In one embodiment, the instant pharmaceutical composition contains a per dosage unit of from about 0.01 to about 50 mg/kg of compound, and preferably from about 0.05 to about 20 mg/kg. Methods are known in the art
30 for determining therapeutically effective doses for the instant pharmaceutical composition. The effective dose for administering the pharmaceutical composition to a human, for example, can be determined mathematically from the results of animal studies. Furthermore, compounds of the present invention can be administered in intranasal form via topical use of suitable intranasal

vehicles, or via transdermal routes, using those forms of transdermal skin patches well known to those of ordinary skill in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen.

5

Oral dosage forms

Because of their ease of administration, tablets and capsules represent an advantageous oral dosage unit form, wherein solid pharmaceutical carriers are employed. If desired, tablets may be sugar-coated or enteric-coated by standard techniques.

10

For liquid forms the active drug component can be combined in suitably flavored suspending or dispersing agents such as the synthetic and natural gums, for example, tragacanth, acacia, methyl-cellulose and the like. Other dispersing agents that may be employed include glycerin and the like.

15

Skin Care Compositions

In one embodiment of the present invention, compounds of the present invention are formulated as skin care compositions, particularly for use in treating psoriasis.

there is no interaction which would substantially reduce the cosmetic or pharmaceutical efficacy of the composition under ordinary use situations.

5 Preferably the skin care compositions of the present invention are topical compositions., ie., they are applied topically by the direct laying on or spreading of the composition on skin. Preferably such topical compositions comprise a cosmetically- or pharmaceutically-acceptable topical carrier.

These include, but are not limited to, lotions, creams, beach oils, gels, sticks, sprays, ointments, pastes, mousses, and cosmetics; hair care compositions such as shampoos and conditioners; and personal cleansing compositions.

15 Preferably the carrier is a cosmetically- or pharmaceutically-acceptable aqueous or organic solvent. Water is a preferred solvent. Examples of suitable organic solvents include: propylene glycol, polyethylene glycol (200-600), polypropylene glycol (425-2025), propylene glycol-14 butyl ether, glycerol, 1,2,4butanetriol, sorbitol esters, 1,2,6-hexanetriol, ethanol, isopropanol, butanediol, and mixtures thereof. Such solutions useful in the present invention
20 preferably contain from about 0.001% to about 25% of the active compound, more preferably from about 0.1% to about 10% more preferably from about 0.5% to about 5%; and preferably from about 50% to about 99.99% of an acceptable aqueous or organic solvent, more preferably from about 90% to about 99%.

Skin care compositions of the present invention may further include a wide variety of additional oil-soluble materials and/or water-soluble materials conventionally used in topical compositions, at their art-established levels. Such additional components include, but are not limited to: thickeners, pigments,
30 fragrances, humectants, proteins and polypeptides, preservatives, pacifiers, penetration enhancing agents, collagen, hylauronic acid, elastin, hydrolysates, primrose oil, jojoba oil, epidermal growth factor, soybean saponins, mucopolysaccharides, Vitamin A and derivatives thereof, Vitamin B2, biotin, pantothenic acid, Vitamin D, and mixtures thereof.

Inhalant compositions

In a particular embodiment, the instant pharmaceutical composition is administered by inhalation. For inhalation therapy, the composition may be in a solution useful for administration by metered dose inhalers, or in a form suitable for a dry powder inhaler or insufflator. More particularly, the instant composition is conveniently delivered in the form of an aerosol spray delivered, for example from a pressurized container, a pack or a nebuliser, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas inside such container. The dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges made of a pharmaceutically acceptable material such as gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

Coadministration Of Pharmaceutical Agents

In a preferred embodiment of this invention, VEGF-R selective agents of the present invention are advantageously co-administered with at least one other anti-tumor agent to facilitate eradication or stasis of a malignancy. For example, but not to limit the present invention, an anti-VEGF-R compound of the present invention, acting, for example, as anti-angiogenic compound, can be administered in a dosing regimen with a cytotoxic compound, such as a DNA alkylating agent. Preferred anti-tumor agents are selected from the group consisting of cladribine (2-chloro-2'-deoxy-(beta)-D-adenosine), Chlorambucil (4-[bis(2-chlorethyl)amino]benzenebutanoic acid), DTIC-Dome (5-(3,3-dimethyl-1-triazeno)-imidazole-4-carboxamide), platinum chemotherapeutics and nonplatinum chemotherapeutics. Platinum containing anti-tumor agents include, but are not limited to, cisplatin (cis-dichlorodiamineplatinum). Non-platinum containing anti-tumor agents include, but are not limited to, cyclophosphamide, fluorouracil, epirubicin, methotrexate, vincristine, doxorubicin, bleomycin, and etoposide. Each anti-tumor agent is administered within therapeutically effective amounts, which are well known in the art, and vary based on the agent used, the type of malignancy, and other conditions

Specific Synthetic Examples

The invention can be better understood by way of the following examples. These examples are representative of the preferred embodiments, but are not to be construed as limiting the scope of the invention.

General

¹H NMR spectra were measured on a Bruker AC-300 (300 MHz) spectrometer using tetramethylsilane as an internal standard. Elemental analyses were obtained by Quantitative Technologies Inc. (Whitehouse, New Jersey), and the results were within 0.4% of the calculated values unless otherwise mentioned. Melting points were determined in open capillary tubes with a Thomas-Hoover apparatus and were uncorrected. Optical rotations were measured at 25 °C with an Autopol III polarimeter. Electrospray mass spectra (MS-ES) were recorded on a Hewlett Packard 59987A spectrometer. High resolution mass spectra (HRMS) were obtained on a Micromass Autospec. E. spectrometer.

VEGF-R Screening Assay

5 A kinase reaction mixture was prepared containing 50 mM Tris-HCl
pH=8, 10 mM MgCl₂, 0.1 mM Na₃PO₄, 1 mM DTT, 10 μM ATP, 0.025 μM
biotinylated peptide substrate and 0.8 μCuries per well ³³P-γ-ATP [2000-3000
Ci/mmol]. 70 μl of the kinase reaction mixture was dispensed into the well of a
streptavidin coated FlashPlate™ (Cat. # SMP103, NEN, Boston, MA). Then 1 μl
10 of test compound stock in 100% DMSO was added to the wells resulting in a

final concentration of 1% DMSO in the reaction with a 100 μ l final reaction volume. Next, soluble rat tyrosine kinase containing an N-terminal 6XHIS tag was diluted in 50 mM Tris-HCl pH=8.0, 0.1% BSA at a concentration of 5 ng per microliter and 30 μ l (150ng enzyme per test well) was added to each well to
5 initiate the reaction. The reaction was incubated for one hour at 30°C. At the end of the 1-hour incubation, the reaction was terminated by aspirating the reaction mixture from the plate and washing the wells twice with PBS containing 100 mM EDTA. The PLC1 biotinylated peptide substrate becomes immobilized on the Flashplate™ and the incorporation of ^{33}P - γ -ATP was measured by reading
10 the plate on a scintillation counter. Inhibition of the enzymatic activity of the VEGF-R was measured by observing a reduced amount of ^{33}P - γ -ATP incorporated into the immobilized peptide.

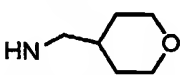

IC₅₀ data for VEGF-R and CDK are shown in Tables 1 to 3. IC₅₀ values
15 listed as >10 or >100 indicate no observed 50% inhibition at the highest dose tested, nor was an inhibition maxima observed. The term n.d. means not tested.

Kinase Selectivity Assays

Assays to test compound inhibition of other kinases were performed using methods that measure the amount of phosphorylation of a biotinylated peptide substrate. Biotinylated peptide substrates were selected from the literature as appropriate for the enzyme being evaluated. The general procedure used to assay for kinase activity is as follows: A kinase reaction mix was prepared in 50 mM Tris-HCl pH=8, 10 mM MgCl₂, 0.1 mM Na₃VO₄, 1 mM DTT, 5-10 μM ATP, 0.25-1 μM biotinylated peptide substrate, 0.2-0.8 μCuries per well ³³P-γ-ATP [2000-3000 Ci/mmol]. Assay conditions vary slightly for each protein kinase, for example, insulin receptor kinase requires 10 mM MnCl₂ for activity and Calmodulin-dependent protein kinase requires calmodulin and 2 mM CaCl₂. The reaction mixture was dispensed into the wells of a streptavidin coated Flashplate and 1 μl drug stock in 100% DMSO was added to a 100 μl reaction volume resulting in a final concentration of 1% DMSO in the reaction. Enzyme was diluted in 50 mM Tris-HCl pH=8.0, 0.1% BSA and added to each well. The reaction was incubated for one hour at 30°C in the presence of compound. After one hour the reaction mix was aspirated from the plate and the plate was washed with PBS containing 100 mM EDTA. The plate was read on a scintillation counter to determine ³³P-γ-ATP incorporated into the immobilized peptide. Test compounds were assayed in duplicate at 8 concentrations [100 μM, 10 μM, 1 μM, 100 nM, 10 nM, 1 nM, 100 pM, 10 pM]. A maximum and minimum signal for the assay was determined on each plate. The IC₅₀ was calculated from the dose response curve of the percent inhibition of the maximum signal in the assay according to the formula [max signal – background/test compound signal – background (100) = % inhibition] by graphing the percent inhibition against the log concentration of test compound. Known inhibitor compounds appropriate for the kinase being assayed were also included on each plate.

Definition and Source of Kinase Enzymes.

VEGF-R (vascular endothelial growth factor receptor-2) is a fusion protein containing a polyhistidine tag at the N-terminus followed by amino acids 786-1343 of the rat VEGF-R2 kinase domain (GenBank Accession #U93306).

CDK1 (cyclin dependent kinase 1) is isolated from insect cells expressing both the human CDK1 catalytic subunit and its positive regulatory subunit cyclin B (New England Biolabs, Beverly, MA, Cat. #6020). CDK4 (cyclin dependent kinase 4) contains amino acids 769 to 921 of the mouse R6 protein found in the

5 GST-retinoblastoma protein construct (Santa Cruz Biotechnology, Santa Cruz, CA; Cat. #SC-4112). Insulin Receptor Kinase consists of residues 941-1313 of the cytoplasmic domain of the beta-subunit of the human insulin receptor (BIOMOL, Plymouth Meeting, PA, Cat. #SE-195). EXAMPLE 120

Cell Proliferation Assay

- 5 The ability of a test compound to inhibit the proliferation of cell growth was determined by measuring incorporation of ¹⁴C-labelled thymidine into newly synthesized DNA within the cells. This method was used on cell lines derived from carcinomas originating from several tissues such as HeLa cervical adenocarcinoma (American Type Culture Collection (ATCC), Virginia, Cat.
- 10 #CCL-2), A375 malignant melanoma (ATCC CRL-1619), SK-OV-3 ovarian adenocarcinoma (ATCC HTB-77) HCT-116 colon carcinoma (CCL-247) and PC-3 prostate adenocarcinoma (ATCC CRL-1435). The method was also used on primary cells such as HUVEC endothelial cells (ATCC CRL-1730). In this way the effect of a compound on cell growth of cells with many different
- 15 phenotypes can be determined. Cells were trypsinized and counted and 3000-

8000 cells were added to each well of a 96-well CytoStar tissue culture treated scintillating microplate (Amersham #RPNQ0160) in complete medium in a volume of 100 μ l. Cells were incubated for 24 hours in complete medium at 37°C in an atmosphere containing 5% CO₂.

5

Next, 1 μ l of test compound in 100% DMSO was added to the wells of the plate. DMSO only was added to control wells. Cells were incubated for 24 more hours in complete medium at 37°C in an atmosphere containing 5% CO₂. Methyl ¹⁴C-thymidine 56 mCi/mmol (NEN #NEC568 or Amersham #CFA532) was diluted in complete medium and 0.2 μ Ci/well was added to each well of the CytoStar plate in a volume of 20 μ l. The plate was incubated for 24 hours at 37°C plus 5% CO₂ in drug plus ¹⁴C-thymidine.

10

The contents of the plate were discarded into a ¹⁴C radioactive waste container by inverting the plate and the plate was washed twice with 200 μ l PBS. 200 μ l of PBS is then added to each well. The top of the plate was sealed with a transparent plate sealer and a white plate backing sealer (Packard #6005199) was applied to the bottom of the plate. The degree of Methyl ¹⁴C-thymidine incorporation was quantified on a Packard Top Count.

EXAMPLE 121

Rat Aortic Ring Assay

The rat aortic ring assay is a rapid *in vitro* assay that measures new capillary growth in an environment that closely approximates the *in vivo* conditions of the extracellular matrix. The assay was performed as described (Nicosia, RF and Ottinetti, A. Growth of new microvessels in serum-free matrix culture of rat aorta. *Lab Invest.*, 63: 115-122, 1990). Thoracic aortas were removed from 1 to 2-month old male Sprague-Dawley rats and transferred to a culture dish containing serum-free MCDB 131 medium (Clonetics). Extraneous tissue was removed and the aorta was sectioned into rings approximately 1mm long and rinsed 8-10 times in serum-free medium. A solution of sterile 1.5% agarose (Type VI-A, Sigma, St. Louis, MO) was added to the wells of a 6-well plate. The wells were filled with clotting fibrinogen solution and an aortic ring was transferred into the well positioned with the lumen oriented horizontally in the center of the fibrin gel solution. The fibrinogen solution was prepared in MCDB 131 medium with bovine fibrinogen at 3 mg/ml. Clotting was initiated by adding 20 μ l of a 50 NIH units/ml bovine thrombin solution and the fibrin gel generally formed within 30 seconds. The fibrinolytic inhibitor amino-n-caproic acid was added to the culture medium at 300 μ g/ml (microgram per milliliter) for the first four days of the assay and at 50 μ g/ml from day 5 to day 8. Once the fibrin gel solution solidified, 5 ml of serum-free MCDB 131 media containing 100 μ g/ml penicillin, 100 μ g/ml streptomycin and 0.25 μ g/ml amphotericin B was added to each well. Explants were incubated at 37°C with 5% CO₂ for 8 days. Medium was replaced every 2-3 days and the assay was analyzed on day 8. Inhibition of vascular sprouting was measured by adding test compounds diluted in DMSO. The final concentration of DMSO in the assay did not exceed 0.2%. As shown in Table 6, the degree of inhibition was quantified using the Vessels image analysis package as described (Nissanov, J, Tuman, RW, Gruver,

LM and Fortunato, JM. Automatic vessel segmentation and quantification of the rat aortic ring assay of angiogenesis. *Lab. Invest.* 73, 734-739, 1995).

EXAMPLE 122

In vitro AUTOPHOSPHORYLATION assay for kinase inhibition

VEGF-R autophosphorylation assay

Growth factor receptors are activated following binding of their cognate ligands which catalyzes autophosphorylation of the receptor. The VEGF receptor is autophosphorylated upon binding to VEGF (Tessler, S., Rockwell, P., Hicklin, D., Cohen, T., Levi, B.-Z., Witte, L. Lemischka, I.R. & Neufeld, G. (1994) *J. Biol. Chem.* 269, 12456-12461) and activation of signal transduction then occurs (Heldin, C.-H. (1995) *Cell* 80, 213-223). As autophosphorylation is essential for a signal to be transduced, an assay to quantitate the degree of phosphorylation of the VEGF receptor measures the ability of a test compound to directly inhibit activation of the VEGF-R and eliminates the possibility of substrate interactions.

A kinase reaction mixture is prepared containing 50 mM Tris-HCl pH=8, 10 mM MgCl₂, 0.1 mM Na₃VO₄, 1 mM DTT, 5-10 μ M ATP, and 0.8 μ Curies per well ³³P- γ -ATP [2000-3000 Ci/mmol]. 70 μ l of the kinase reaction mixture is dispensed into the well of an NTA-Nickel coated FlashPlate™ (Cat. # SMP107, NEN, Boston, MA). Then 1 μ l of test compound in 100% DMSO is added to the wells resulting in a final concentration of 1% DMSO in the reaction (100 μ l final reaction volume includes subsequent enzyme solution). Then soluble rat tyrosine kinase containing an N-terminal 6XHIS tag is diluted in 50 mM Tris-HCl pH=8.0, 0.1% BSA at a concentration of 5 ng per microliter and 30 μ l (150ng per test well) is added to each well to initiate the reaction. The reaction is incubated for one hour at 30°C. At the end of the 1-hour incubation, the reaction is terminated by aspirating the reaction mixture from the plate and

washing the wells twice with PBS containing 100 mM EDTA. The 6XHIS-VEGF receptor becomes immobilized on the Flashplate™ and the incorporation of ³³P-γ-ATP via autophosphorylation is measured by reading the plate on a scintillation counter. Inhibition of the enzymatic activity of the VEGF-R is measured by observing a reduced amount of ³³P-γ-ATP incorporated into the immobilized enzyme.

EXAMPLE 123

In vivo models – Inhibition of Tumor Growth

The *in vivo* effect of a compound on the growth of human tumor cells can be evaluated by implanting human tumor cells into the hindflank of athymic mice and administering test compound to the mice. Such assays are useful in identifying and confirming compounds that are useful for inhibiting angiogenesis or to identify compounds that can inhibit VEGF activity and therefor are useful for treating a variety of cancers or other diseases associated with abnormal or aberrant angiogenesis, such as those diseases discussed *supra*. Human tumor cells originating from a variety of different cancer types, such as A375 human melanoma cells, were implanted subcutaneously into the hindflank of male athymic mice (Charles River) and allowed to establish a sizeable tumor for 6-10 days as determined by caliper measurements. Test compound was then administered by injecting the compound formulated in an appropriate vehicle, here saline was used as the vehicle, intraperitoneally into the mice once a day for 30 days. The test compound can also be administered by other routes such as orally, sub cutaneously or by intravenous infusion. The size of the tumor in this study was measured every four days and the degree of inhibition was determined by comparing drug-treated animals to animals that were injected with vehicle only. Figure 1 illustrates the results of one study with **Cmd 33** indicating a delay of tumor size progression. Similarly the compounds of this invention can be tested in other known models of aberrant angiogenesis, such as models of retinopathy, endometriosis, psoriasis and the like.

The synergistic action or enhancement of conventional chemotherapeutic agent by a test compound can also be determined with this model by comparing animals treated with the standard therapy alone to animals treated with test

compound plus the same standard therapy. An additive effect on the delay of tumor growth will be observed if synergistic action due to test compound is occurring.
